The present invention relates to a series of pyrimidinyl substituted fused-pyrrolyl compounds, pharmaceutical compositions and methods for use thereof. More
10 particularly, the pyrimidinyl substituted 7-azaindolyl compounds of the present invention are kinase inhibitors useful in treating or ameliorating a kinase mediated, angiogenesis-mediated or hyperproliferative disorder.

BACKGROUND OF THE INVENTION

In general, protein kinases are the largest set of structurally related phosphoryl
15 transferases, have highly conserved structures and catalytic functions and may be categorized into families by the substrates they phosphorylate (e.g., protein-tyrosine, protein-serine/threonine, histidine and the like) and are responsible for the control of a wide variety of cellular signal transduction processes.

20 IGFR-1, Zap-70, Bmx, Btk, CHK (Csk homologous kinase), CSK (C-terminal Src Kinase), Itk-1, Src (c-Src, Lyn, Fyn, Lck, Syk, Hck, Yes, Blk, Fgr and Frk), Tec, Txk/Rlk, Abl, EGFR (EGFR-1/ErbB-1, ErbB-2/NEU/HER-2, ErbB-3 and ErbB-4), FAK, FGF1R (also FGFR1 or FGR-1), FGF2R (also FGR-2), MET (also Met-1 or c-MET), PDGFR- α , PDGFR- β , Tie-1, Tie-2 (also Tek-1 or Tek), VEGFR1 (also FLT-1),
25 VEGFR2 (also KDR), FLT-3, FLT-4, c-KIT, JAK1, JAK2, JAK3, TYK2, LOK, RET, TRKA, PYK2, ALK (Anaplastic Lymphoma Kinase), EPHA (1-8), EPHB (1-6), RON, Fes, Fer or EPHB4 (also EPHB4-1).

Examples of protein-serine/threonine kinases include, but are not limited to, Ark, ATM (1-3), CamK (1-4), CamKK, Chk1 and 2 (Checkpoint kinases), CK1, CK2,
30 Erk, IKK-1 (also IKK-ALPHA or CHUK), IKK-2 (also IKK-BETA), Ilk, Jnk (1-3),

LimK (1 and 2), MLK3, Raf (A, B, and C), CDK (1-10), PKC (including all PKC subtypes), Plk (1-3), NIK, Pak (1-3), PDK1, PKR, RhoK, RIP, RIP-2, GSK3 (A and B), PKA, P38, Erk (1-3), PKB (including all PKB subtypes) (also AKT-1, AKT-2, AKT-3 or AKT3-1), IRAK1, FRK, SGK, TAK1 or Tpl-2 (also COT).

5 Protein kinases play very important roles in the normal regulation of cell growth. However, as a result of either mutation or overexpression of the tyrosine kinases (receptor or non-receptor) or the ligands of the receptor tyrosine kinases, signaling can become deregulated, resulting in uncontrolled cell proliferation leading to cancer or a related disease, disorder or syndrome.

10 Protein kinases catalyze and regulate the process of phosphorylation, whereby the kinases covalently attach phosphate groups to proteins or lipid targets in response to a variety of extracellular signals: hormones, neurotransmitters, growth and differentiation factors, cell cycle events, environmental stresses, nutritional stresses and the like.

15 Phosphorylation modulates or regulates a variety of cellular processes such as proliferation, growth, differentiation, metabolism, apoptosis, motility, transcription, translation and other signaling processes. Uncontrolled signaling for cell growth due to defective control of protein phosphorylation has also been implicated in a number of diseases and disease conditions, such as osteoarthritis, rheumatoid arthritis, synovial pannus invasion in arthritis, multiple sclerosis, myasthenia gravis, diabetes mellitus, diabetic angiopathies or retinopathy, inflammatory bowel disease, Crohn's disease, ulcerative colitis, transplant or bone marrow transplant rejection, lupus, chronic pancreatitis, cachexia, septic shock, skin diseases or disorders (such as papilloma formation, psoriasis, dermatitis, eczema, seborrhea and the like), central nervous system diseases (such as Alzheimer's disease, Parkinson's disease, depression and the like), cancers (such as glioma cancers, epidermoid cancers, head and neck cancers, lung cancers, breast cancers, colorectal cancers, prostate cancers, gastric cancers, esophageal cancers or papillocarcinomas and the like and associated pathologies such as unregulated cell proliferation, tumor growth or vascularization or metastatic cancer cell invasion and migration and the like or leukemias or lymphomas), ocular diseases (such as macular degeneration, diseases of the cornea, glaucoma and the like), viral infections (such as cytomegalovirus CMV), heart disease (such as atherosclerosis, neointima

formation or transplantation-induced vasculopathies (such as restenosis and the like), lung or pulmonary diseases (such as allergic-asthma, lung fibrosis or complications resulting from chronic obstructive pulmonary disorder and the like) or kidney or renal diseases (such as acute, subacute or chronic forms of glomerulonephritis or

5 membranoproliferative glomerulonephritis, glomerulosclerosis, congenital multicystic renal dysplasia, kidney fibrosis and the like). Therefore, kinase inhibitors have potential use as therapeutic agents.

The tyrosine kinases can further be categorized by whether they are receptor tyrosine kinases or non-receptor tyrosine kinases. The receptor tyrosine kinases span the

10 cell membrane with a ligand interacting domain protruding from the cell, with a hydrophobic trans-membrane domain, and a cytoplasmic domain that contains the catalytic kinase domain and other regulatory sequences. Non-receptor tyrosine kinases are often myristylated or modified by the addition of other hydrophobic moieties that allow them to be anchored to the cell membrane.

15 Human cytomegalovirus (CMV) is a widespread opportunistic human herpes virus that causes severe and fatal diseases in those who are immune compromised and in transplant recipients. CMV is also a leading cause of atherosclerosis and virally mediated birth defects. The human CMV uses the EGFR receptor to enter cells during infection, EGFR is autophosphorylated and the downstream signal transduction pathway components are activated; however, the EGFR specific inhibitor tyrphostin AG1478 has been shown to reduce the viral load in cells that were infected in the presence of the tyrphostin (Wang, et al., Nature, 24 July 2003, Vol 424). Accordingly, potent EGFR selective inhibitors may be useful in anti-CMV therapy.

20 Uncontrolled cell proliferation is the insignia of cancer. Cell proliferation in response to various stimuli is manifested by a deregulation of the cell division cycle, the process by which cells multiply and divide. Tumor cells typically have damage to the genes that directly or indirectly regulate progression through the cell division cycle.

25 CDKs constitute a class of enzymes that play critical roles in regulating the transitions between different phases of the cell cycle, such as the progression from a quiescent stage in G₁ (the gap between mitosis and the onset of DNA replication for a new round of cell division) to S (the period of DNA synthesis), or the progression from G₂ to M phase, in which active mitosis and cell-division occur. See, e.g., the articles

compiled in *Science*, vol. 274 (1996), p. 1643-1677; and *Ann. Rev. Cell Dev. Biol.*, vol. 13 (1997), pp. 261-291. CDK complexes are formed through association of a regulatory cyclin subunit (e.g., cyclin A, B1, B2, D1, D2, D3, and E) and a catalytic kinase subunit (e.g., cdc2 (CDK1), CDK2, CDK4, CDK5, and CDK6). As the name 5 implies, the CDKs display an absolute dependence on the cyclin subunit in order to phosphorylate their target substrates, and different kinase/cyclin pairs function to regulate progression through specific phases of the cell cycle.

The D cyclins are sensitive to extracellular growth signals and become activated in response to mitogens during the G₁ phase of the cell cycle. CDK4/cyclin D plays an 10 important role in cell cycle progression by phosphorylating, and thereby inactivating, the retinoblastoma protein (Rb). Hypophosphorylated Rb binds to the E2F family of transcriptional regulators, but upon hyperphosphorylation of Rb by CDK4/cyclin D, these transcription factors are released to activate genes whose products are responsible for S phase progression. Rb phosphorylation and inactivation by CDK4/cyclin D 15 permit passage of the cell beyond the restriction point of the G₁ phase, whereby sensitivity to extracellular growth or inhibitory signals is lost and the cell is committed to cell division. During late G₁, Rb is also phosphorylated and inactivated by CDK2/cyclin E, and recent evidence indicates that CDK2/cyclin E can regulate 20 progression into S phase through a parallel pathway that is independent of Rb phosphorylation (see Lukas et al., "Cyclin E-induced S Phase Without Activation of the pRb/E2F Pathway," *Genes and Dev.*, vol. 11 (1997), pp. 1479-1492).

The progression from G₁ to S phase, accomplished by the action of CDK4/cyclin D and CDK2/cyclin E, is subject to a variety of growth regulatory mechanisms, both negative and positive. Growth stimuli, such as mitogens, cause 25 increased synthesis of cyclin D1 and thus increased functional CDK4. By contrast, cell growth can be "reigned in", in response to DNA damage or negative growth stimuli, by the induction of endogenous inhibitory proteins. These naturally occurring protein inhibitors include p21^{WAF1/CIP1}, p27^{KIP1}, and the p16^{INK4} family, the latter of which inhibit CDK4 exclusively (see Harper, "Cyclin Dependent Kinase Inhibitors," *Cancer Surv.*, vol. 29 (1997), pp. 91-107). Aberrations in this control system, particularly those 30 that affect the function of CDK4 and CDK2, are implicated in the advancement of cells to the highly proliferative state characteristic of malignancies, such as familial

melanomas, esophageal carcinomas, and pancreatic cancers (see, e.g., Hall and Peters, "Genetic Alterations of Cyclins, Cyclin-Dependent Kinases, and CDK Inhibitors in Human Cancer," *Adv. Cancer Res.*, vol. 68 (1996), pp. 67-108; and Kamb et al., "A Cell Cycle Regulator Potentially Involved in Genesis of Many Tumor Types," *Science*, vol. 264 (1994), pp. 436-440). Over-expression of cyclin D1 is linked to esophageal, breast, and squamous cell carcinomas (see, e.g., DelSal et al., "Cell Cycle and Cancer: Critical Events at the G₁ Restriction Point," *Critical Rev. Oncogenesis*, vol. 71 (1996), pp. 127-142).

Angiogenesis plays a role in various processes including development of the vasculature, wound healing and maintenance of the female reproductive system. Pathological angiogenesis is associated with disease states such as cancer, diabetic retinopathy, rheumatoid arthritis, endometriosis and psoriasis. Solid-tumor cancers, in particular, are dependent on angiogenesis for their growth. The vascular endothelial growth factors (VEGFs) are mediators of both normal and pathologic angiogenesis.

VEGF transmits signals into cells through their cognate receptors, which belong to the receptor tyrosine kinase (RTK) family of transmembrane receptors. These receptors are tripartite, consisting of an extracellular ligand-binding domain, a transmembrane domain, which anchors the receptor in the membrane of the cell, and an intracellular tyrosine kinase domain.

One subfamily of RTKs comprises the receptors Flt1/VEGF-R1 and KDR/Flk1/VEGF-R2, which bind VEGFs. Binding of the VEGF ligand to the receptor results in stimulation of the receptor tyrosine kinase activity and transduction of biological signals into the cell. The KDR/Flk1/VEGF-R2 receptor mediates the biological activities of mitogenesis and proliferation of endothelial cells while the Flt1/VEGF-R1 receptor mediates functions such as endothelial cell adhesion. Inhibition of KDR/Flk1/VEGF-R2 signalling has been shown to inhibit the process of angiogenesis. Inhibitors of this receptor are likely useful in controlling or limiting angiogenesis.

Another RTK subfamily, the epidermal growth factor receptor (EGFR) tyrosine-kinase family, includes the receptors EGFR (also referred to as EGFR-1 or Erb-B1), HER-2 (or neu), EGFR3 and EGFR4. The Epidermal Growth Factor (EGF) and,

Transforming Growth Factor- α (TGF- α) and HER-2 ligand heregulin are three of the ligands that bind to the EGFR receptors.

For example, EGFR overexpression or mutation of one or more EGFR kinase family members has been commonly involved in cancer and other diseases

5 characterized by uncontrolled or abnormal cell growth. Deregulation of EGFR has also been associated with epidermoid tumors, head and neck tumors, breast tumors and tumors involving other major organs. Diseases associated with increased EGFR expression include proliferative glomerulonephritis, diabetes-induced renal disease and chronic pancreatitis. Overexpression of HER2 has been associated with breast and
10 ovarian cancer. Diseases associated with the overproduction of TGF- α , rather than overexpression of EGFR, include psoriasis, a cell-proliferative skin disorder. Since EGFR expression levels in uterine tissues are elevated during implantation of a fertilized egg, an EGFR inhibitor may also have potential use as a contraceptive to reduce fertility.

15 Aurora kinases are highly conserved and found in all organisms where they function to regulate microtubule dynamics during the M phase of the cell cycle. Aurora-A associates with the centrosome around the pericentriolar material, as well as the microtubules at the bipolar mitotic-spindle poles and the midbody microtubules. The kinase is involved in centrosome separation, duplication and maturation as well as
20 in bipolar spindle assembly and stability. Aurora-A is overexpressed in a number of different human cancers and tumor cell lines. Overexpression of Aurora is sufficient to induce growth in soft agar and transforms cells making them tumorigenic. Inhibition of Aurora activity results in centrosome/chromosome segregation defects leading to monopolar spindles and polyploidy which arrests cells and induces apoptosis.

25 Germline mutations in the RET proto-oncogene are responsible for multiple endocrine neoplasia type 2, a dominantly inherited cancer syndrome. Moreover, somatic rearrangements of RET are causally involved in the genesis of papillary thyroid carcinoma. Rearrangements of RET in papillary thyroid carcinoma (called RET/PTC), juxtapose the region coding for the tyrosine kinase domain with the 5 prime-terminal
30 regions of a variety of unrelated genes. RET/PTC oncogenes code for fusion proteins that display a constitutive tyrosine kinase activity. The receptor tyrosine kinase encoded by the RET gene normally functions as the subunit of a complex that binds

four distinct ligands and activates a signalling network crucial for neural and kidney development.

There is a need, for small-molecule compounds that may be readily synthesized and are potent inhibitors of one or more CDK, VEGF-R2 kinase, HER2 kinase, Aurora-A kinase, or RET receptor kinase that possess anti-tumor cell proliferation activity, and as such are useful in treating or ameliorating a CDK, VEGF-R2 kinase, HER2 kinase, Aurora-A kinase, or RET receptor kinase mediated, angiogenesis-mediated or hyperproliferative disorder.

SUMMARY OF THE INVENTION

Accordingly, one object of the invention is to attain compounds and drug compositions that inhibit the activity of one or more of the CDK, VEGF-R2 kinase, HER2 kinase, Aurora-A kinase, or RET kinase receptors. A further object is to provide an effective method of treating cancer indications and kinase mediated, angiogenesis-mediated or hyperproliferative disorders through CDK, VEGF-R2, HER2, Aurora-A or RET inhibition. Another object is to achieve pharmaceutical compositions containing compounds effective to inhibit the proliferation of cancer cells. These and other objects and advantages of the invention, which will become apparent in light of the detailed description below, are achieved through use of the compounds of the invention described below.

Pharmaceutical Preparations & Methods of Use

10 Pharmaceutical compositions according to the invention may, alternatively or in addition to a compound of Formula (I), comprise as an active ingredient a pharmaceutically acceptable salt of a compound of Formula (I), (Ia) or (Ib) or an ester, prodrug or pharmaceutically active metabolite of such a compound or salt.

A compound of Formula (I) as an active ingredient further includes a radio-labeled compound of Formula (I), whereby at least one hydrogen atom of the compound of Formula (I) is replaced with a deuterium or tritium atom. Other labeling techniques known to those skilled in the arts may also be used.

15 "Composition(s)" refers to a product containing one or more compounds of Formula (I) or a form thereof (such as a product comprising the specified ingredients in the specified amounts, as well as any product which results, directly or indirectly, from such combinations of the specified ingredients in the specified amounts).

20 "Pharmaceutically acceptable" refers to molecular entities and components used herein which are of sufficient purity and quality such that, when appropriately administered to an animal or a human, the composition does not produce an adverse, allergic or other untoward reaction. Accordingly, a pharmaceutically acceptable composition or medicament for either human use (clinical and over-the-counter) or veterinary use are equally included within the scope of the present invention.

25 The compounds of the present invention may be present in the form of salts. For use in medicines, a salt form for a compound of this invention refers to acidic/anionic or basic/cationic salt forms.

30 Suitable salt forms include acid addition salts which may, for example, be formed by mixing a solution of the compound according to the invention with a

solution of an acid such as hydrochloric acid, sulphuric acid, fumaric acid, maleic acid, succinic acid, acetic acid, benzoic acid, citric acid, tartaric acid, carbonic acid, phosphoric acid and the like.

Furthermore when the compounds of the present invention carry an acidic moiety, suitable salts thereof may include alkali metal salts, e.g. sodium or potassium salts; alkaline earth metal salts, e.g. calcium or magnesium salts; and salts formed with suitable organic ligands, e.g. quaternary ammonium salts. Thus, representative salts include the following: acetate, benzenesulfonate, benzoate, bicarbonate, bisulfate, bitartrate, borate, bromide, calcium, camsylate (or camphosulphonate), carbonate, chloride, clavulanate, citrate, dihydrochloride, edetate, fumarate, gluconate, glutamate, hydrabamine, hydrobromine, hydrochloride, iodide, isothionate, lactate, malate, maleate, mandelate, mesylate, nitrate, oleate, pamoate, palmitate, phosphate/diphosphate, salicylate, stearate, sulfate, succinate, tartrate, tosylate, trichloroacetate, trifluoroacetate and the like.

Compositions in accordance with the invention inhibit the kinase activity of CDK, VEGF-R2 kinase, HER2 kinase, Aurora-A kinase, or RET receptor kinase or kinase complexes.

Preferred compositions of the invention contain compounds having an inhibition constant against a CDK, VEGF-R2 kinase, HER2 kinase, Aurora-A kinase, or RET receptor kinase of about 25 μM or less, more preferably of about 10 μM or less, even more preferably of about 1 μM or less, and most preferably of about 0.5 μM or less.

Certain compounds of Formula (I), (Ia) or (Ib) may exist in various stereoisomeric or tautomeric forms. The present invention encompasses all such CDK, VEGF-R2 kinase, HER2 kinase, Aurora-A kinase, or RET receptor kinase inhibiting compounds, including active compounds in the form of essentially pure enantiomers, racemic mixtures, pure geometric isomers (such as *cis* and *trans* stereoisomers), tautomers, isomers or equilibrated mixtures thereof.

The present invention indeed contemplates compounds of various isomers and mixtures thereof. The term "isomer" refers to compounds that have the same composition and molecular weight but differ in physical and/or chemical properties. Such substances have the same number and kind of atoms but differ in structure. The

structural difference may be in constitution (geometric isomers) or in an ability to rotate the plane of polarized light (optical isomers, or enantiomers).

The term "stereoisomer" refers to isomers of identical constitution that differ in the arrangement of their atoms in space. Enantiomers are stereoisomers wherein an

5 asymmetrically substituted carbon atom acts as a chiral center. The term "chiral" refers to a molecule that is not superposable on its mirror image, implying the absence of an axis and a plane or center of symmetry. The term "enantiomer" refers to one of a pair of molecular species that are mirror images of each other and are not superimposable. The term "diastereomer" refers to stereoisomers that are not related as mirror images.

10 The symbols "R" and "S" represent the configuration of substituents around a chiral carbon atom(s). The symbols "R*" and "S*" denote the relative configurations of substituents around a chiral carbon atom(s). Where the compounds of the present application have at least one stereocenter, they accordingly exist as enantiomers. Where the compounds according to the present invention posses two or more

15 stereocenters, they may additionally exist as diastereoisomers. It is to be understood that all such isomers and mixtures thereof are encompassed within the scope to the present invention.

The term "racemate" or "racemic mixture" refers to a compound of equimolar quantities of two enantiomeric species, wherein the compound is devoid of optical

20 activity. The term "optical activity" refers to the degree to which a chiral molecule or nonracemic mixture of chiral molecules rotates the plane of polarized light.

The term "geometric isomer" refers to isomers that differ in the orientation of substituent atoms in relationship to a carbon-carbon double bond, to a cycloalkyl ring or to a bridged bicyclic system. Substituent atoms (other than H) on each side of a

25 carbon-carbon double bond may be in an E or Z configuration. In the "E" (opposite sided) configuration, the substituents are on opposite sides in relationship to the carbon-carbon double bond; in the "Z" (same sided) configuration, the substituents are oriented on the same side in relationship to the carbon-carbon double bond. Substituent atoms (other than H) attached to a carbocyclic ring may be in a cis or trans

30 configuration. In the "cis" configuration, the substituents are on the same side in relationship to the plane of the ring; in the "trans" configuration, the substituents are on

opposite sides in relationship to the plane of the ring. Compounds having a mixture of "cis" and "trans" species are designated "cis/trans".

The compounds of the present invention may be prepared as individual isomers by either isomer-specific synthesis or resolved from an isomeric mixture. Conventional resolution techniques include forming the free base of each isomer of an isomeric pair using an optically active salt (followed by fractional crystallization and regeneration of the free base), forming an ester or amide of each of the isomers of an isomeric pair (followed by chromatographic separation and removal of the chiral auxiliary) or resolving an isomeric mixture of either a starting material or a final product using preparative TLC (thin layer chromatography) or a chiral HPLC column.

The invention also relates to the compounds in different crystalline forms, polymorphic or amorphous forms and (an)hydrous forms and as such are intended to be included in the scope of the invention. In addition, some of the compounds may form solvates with water (i.e., hydrates) or common organic solvents, and such are also intended to be encompassed within the scope of this invention.. It is well known within the pharmaceutical industry that chemical compounds may be isolated in any of such forms by slightly changing the method of purification and/or isolation from the solvents used in the synthetic preparation of such compounds.

The term "prodrug" refers to a metabolic precursor of a compound of Formula (I) (or a salt thereof), that is pharmaceutically acceptable. A prodrug is a functional derivative of a compound which may be inactive when administered to a subject but is converted *in vivo* to an active metabolite compound.

The term "active metabolite" refers to a metabolic product of a compound that is pharmaceutically acceptable and effective for preventing, treating or ameliorating a chronic or acute kinase mediated disease. Conventional procedures for the selection and preparation of suitable prodrug derivatives are described, for example, in "Design of Prodrugs", ed. H. Bundgaard, Elsevier, 1985.

During any of the processes for preparation of the compounds of the present invention, it may be necessary and/or desirable to protect sensitive or reactive groups on any of the molecules concerned. This may be achieved by means of conventional protecting groups, such as those described in Protective Groups in Organic Chemistry, ed. J.F.W. McOmie, Plenum Press, 1973; and T.W. Greene & P.G.M. Wuts, Protective

Groups in Organic Synthesis, 3rd Edition, John Wiley & Sons, 1999. The protecting groups may be removed at a convenient subsequent stage using methods known in the art.

10 The present invention provides a method for treating or ameliorating a kinase mediated disorder in a subject in need thereof comprising administering to the subject an effective amount of a compound of Formula (I).

15 The present invention further provides a method for treating or ameliorating a CDK, VEGF-R2 kinase, HER2 kinase, Aurora-A kinase, or RET receptor kinase mediated disorder in a subject in need thereof comprising administering to the subject an effective amount of a compound of Formula (I) for treating or ameliorating a CDK, VEGF-R2 kinase, HER2 kinase, Aurora-A kinase, or RET receptor kinase mediated disorder.

20 Examples of the method of the present invention include treating or ameliorating a CDK, VEGF-R2 kinase, HER2 kinase, Aurora-A kinase, or RET receptor mediated disorder.

25 Many conventional cytotoxic cancer therapies destroy the rapidly dividing epithelium of the hair follicle and induce alopecia (hair loss). Inhibition of CDK, VEGF-R2 kinase, HER2 kinase, Aurora-A kinase, or RET receptor kinases during conventional chemotherapy may represent a therapeutic strategy for prevention of chemotherapy-induced alopecia by arresting the cell cycle and reducing the sensitivity of epithelial cells to antitumor agents (Davis S.T., et al., Prevention of chemotherapy-induced alopecia in rats by CDK inhibitors, *Science*, 2001, (Jan 5), 291, 5501, 25-6).

30 Accordingly, to be useful in a method for the prevention of chemotherapy-induced alopecia, a CDK, VEGF-R2 kinase, HER2 kinase, Aurora-A kinase, or RET receptor inhibitor compound would have to be cytostatic rather than cytotoxic and be able to hold the cell in a stationary growth phase, thus protecting a hair follicle from the cytotoxic activity of a conventional chemotherapeutic agent being administered at the

same time. In this way, topical application of non-apoptotic CDK, VEGF-R2 kinase, HER2 kinase, Aurora-A kinase, or RET receptor kinase inhibitors represents a potentially useful approach for the prevention of chemotherapy-induced alopecia in cancer patients.

5 Although coronary angioplasty is a highly effective procedure used to reduce the severity of coronary occlusion, its long-term success is limited by a high rate of restenosis. Vascular smooth muscle cell activation, migration and proliferation is largely responsible for restenosis following angioplasty (Ross, R., *Nature*, 1993, 362, 801–809). Recent studies have shown that CDK2 is activated very early after
10 endothelial denudation in a rat carotid artery model of restenosis (Wei, G. L., et al., *Circ. Res.*, 1997, 80, 418–426). Therefore, antiproliferative therapies targeted to CDK other kinases such as a VEGF-R2 kinase, HER2 kinase, Aurora-A kinase, or RET receptor kinase or other components of the cell cycle machinery may be a suitable approach to treat these disorders. One aspect for use of the compounds of the present
15 invention is a method for the treatment or amelioration of restenosis wherein a CDK, VEGF-R2 kinase, HER2 kinase, Aurora-A kinase, or RET receptor kinase inhibitor is impregnated on the surface of an angioplasty balloon or stent, thus targeting drug delivery to the local environment where endothelial and smooth muscle cell proliferation are the leading cause of vascular occlusion following an initial angioplasty
20 and restenosis in the area of a stent's implantation (Eric E. Brooks, Nathanael S. Gray, Alison Joly, Suresh S. Kerwar, Robert Lum, Richard L. Mackman, Thea C. Norman, Jose Rosete, Michael Rowe, Steven R. Schow, Peter G. Schultz, Xingbo Wang, Michael M. Wick and Dov Shiffman, CVT-313, a Specific and Potent Inhibitor of CDK2 That Prevents Neointimal Proliferation, *J. Biol. Chem.*, 1997, 272(46):29207-
25 29211).

30 An embodiment of the present invention includes a prophylactic and therapeutic method for treating or ameliorating a CDK, VEGF-R2 kinase, HER2 kinase, Aurora-A kinase, or RET receptor kinase mediated disorder in a subject in need thereof comprising administering to the subject an effective amount of a compound of Formula (I) or composition thereof. In an embodiment of the invention, the mediated kinase is a CDK, VEGF-R2 kinase, HER2 kinase, Aurora-A kinase, or RET receptor kinase.

The effective amount of the compounds of Formula (I) exemplified in such a method is from about 0.001 mg/kg/day to about 300 mg/kg/day.

“Subject” means an animal, preferably a mammal, most preferably a human, who is a patient or has been the object of treatment, observation or experiment and is at 5 risk of (or susceptible to) developing a disease or disorder or having a disease or disorder related to unregulated kinase activity.

“Effective amount” means that amount of active compound or pharmaceutical agent that will result in improved healing, prevention, improvement treatment, or a decrease in the rate of advancement of a disease or disorder or amelioration of a 10 disease, disorder, or side effect. The term also indicates the amount that could effectively enhance physiological function.

Another aspect of the present invention includes the use of a compound of Formula (I) for the preparation of a medicament for preventing, treating or ameliorating a CDK, VEGF-R2 kinase, HER2 kinase, Aurora-A kinase, or RET receptor kinase 15 mediated disorder in a subject in need thereof.

“Medicament” refers to one or more compounds of Formula (I) or a form thereof used in a product for use in preventing, treating or ameliorating a chronic or acute kinase mediated disease.

“Administering,” with respect to the methods of the present invention, refers to 20 a means for treating, ameliorating or preventing a disease as described herein with a compound specifically disclosed or a compound or prodrug thereof, which would obviously be included within the scope of the invention albeit not specifically disclosed for certain of the instant compounds.

In accordance with the method of the present invention, an individual compound 25 of the present invention or a composition or medicament thereof can be administered at different times during the course of therapy or concurrently in divided or single combination forms.

Such methods further include administering an effective amount of one or more compounds of Formula (I) or a form, composition or medicament thereof with one or 30 more agents at different times during the course of a therapy or concurrently in a combination form.

Prophylactic administration can occur prior to the manifestation of symptoms characteristic of a CDK, VEGF-R2 kinase, HER2 kinase, Aurora-A kinase, or RET receptor kinase associated disease or disorder such that the disease or disorder is prevented or, alternatively, delayed in its progression. The instant invention is therefore 5 to be understood as embracing all such regimes of simultaneous or alternating treatment and the term "administering" is to be interpreted accordingly.

The term "kinase mediated disorder" as used herein, includes, and is not limited to disorders and diseases associated with kinase overactivity and conditions that accompany such diseases. Kinase overactivity includes unregulated cellular mitosis, 10 unregulated cell proliferation and upregulated kinase activity. Disorders and diseases associated with unregulated cell proliferation include cancers (including solid tumors and leukemias such as glioma cancers, epidermoid cancers, head and neck cancers, lung cancers, breast cancers, colorectal cancers, prostate cancers, gastric cancers, esophageal cancers, papillocarcinomas, Kaposi's sarcoma, leukemias and lymphomas), and 15 associated pathologies such as abnormal cell proliferation, unregulated cell proliferation, tumor growth, tumor vascularization, as well as metastatic cancer cell invasion and migration, angiopathy, angiogenesis, and chemotherapy-induced alopecia.

The term "upregulated kinase activity" refers to either 1) increased or unregulated kinase activity or expression, 2) increased kinase expression leading to 5 unwanted cell proliferation, or 3) mutations leading to constitutive activation of the kinase receptor. The existence of an inappropriate or abnormal level or activity of the kinase receptor is determined by procedures well known in the art.

The term "disorders and diseases associated with unregulated cell proliferation" refers to disorders wherein unwanted cell proliferation of one or more subset 10 of cells in a multicellular organism occurs resulting in harm (such as discomfort or decreased life expectancy) to the multicellular organism.

Such cell proliferative disorders can occur in different types of animals and humans and include, but are not limited to, cancers (glioma, lung, breast, colorectal, prostate, gastric and esophageal, leukemias and lymphomas), atherosclerosis, 15 restenosis, psoriasis, papilloma, pulmonary fibrosis, in-stent stenosis, vascular graft restenosis, glomerular nephritis, diabetic retinopathy and rheumatoid arthritis.

Another aspect of the present invention includes a method for inhibiting a cell's unregulated entry into mitosis comprising administering to the cell an effective amount of a compound of Formula (I) or composition thereof for inhibiting CDK, VEGF-R2 20 kinase, HER2 kinase, Aurora-A kinase, or RET receptor kinase activity in the cell.

Another aspect of the present invention includes a method for inhibiting unregulated cell proliferation in a tumor comprising administering to the tumor an effective amount of a compound of Formula (I) or composition thereof for inhibiting CDK, VEGF-R2 kinase, HER2 kinase, Aurora-A kinase, or RET receptor kinase 25 activity in the tumor.

Another aspect of the present invention includes a method for treating or ameliorating chemotherapy induced alopecia in a subject in need thereof comprising

topically administering to the subject a therapeutically effective amount of a compound of Formula (I) or composition thereof.

In the cancer therapeutic field it is common to use a combination of different treatments to cure cancer patients. Therefore, the antiproliferative activity defined herein could be used as a sole therapy or may involve one or more other substances and/or treatments. Such combinational treatment may be achieved by the simultaneous, sequential or separate administration of the individual components. The other component(s) for these conjoint treatments in addition to the antiproliferation therapy defined above may include surgery, radiotherapy or chemotherapy.

Another aspect of the present invention includes a method for use of a compound of Formula (I) or composition thereof advantageously administered in one or more cell anti-proliferation therapies including chemotherapy, radiation therapy, gene therapy or immunotherapy for preventing, treating or ameliorating a kinase mediated disorder.

The term "radiation therapy" refers to a therapy that comprises exposing the patient in need thereof to radiation. The present invention includes a method for administering one or more compounds of Formula (I) or a form, composition or medicament thereof in combination with radiation therapy. Procedures for administering such therapy are known to those skilled in the art. The appropriate scheme of radiation therapy will be similar to those already employed in clinical therapies wherein the radiation therapy is used alone or in combination with other chemotherapeutic agents.

The combination therapy is selected from, e.g., 1) co-administration of a compound of Formula (I) or composition thereof and a chemotherapeutic agent for preventing, treating or ameliorating a kinase mediated disorder, 2) sequential administration of a compound of Formula (I) or composition thereof and a chemotherapeutic agent for preventing, treating or ameliorating a kinase mediated disorder, 3) administration of a composition containing a compound of Formula (I) and a chemotherapeutic agent for preventing, treating or ameliorating a kinase mediated disorder, or, 4) simultaneous administration of a separate composition containing a compound of Formula (I) and a separate composition containing a chemotherapeutic agent for preventing, treating or ameliorating a kinase mediated disorder.

For example, the compounds of this invention may be useful in combination therapies with a chemotherapeutic agent for the treatment of a number of different cancers and advantageously may facilitate the use of a reduced dose of the chemotherapeutic agent that is recommended for a particular cancer or cell proliferation disorder. Therefore, it is contemplated that the compounds of this invention can be used during or after treatment with a particular chemotherapeutic agent.

The term "chemotherapeutic agent" refers to chemotherapeutic agents used to treat a kinase mediated cancer or antiviral agents used to treat cytomegalovirus and includes, and is not limited to, anti-angiogenic agents, anti-tumor agents, cytotoxic agents, inhibitors of cell proliferation, and the like or mixtures thereof.

The appropriate scheme of radiation therapy will be similar to those already employed in clinical therapies wherein the radiation therapy is used alone or in combination with other chemotherapeutics.

Biological Examples

The utility of the compounds to treat or ameliorate a CDK, VEGF-R2 kinase; HER2 kinase, Aurora-A kinase, or RET receptor kinase mediated disorder was determined using the following procedures.

Selected compounds from the above example were investigated for their kinase activity. A panel of protein kinases, including CDK1, VEGF-R2, Aurora-A, RET and HER2 were used. The individual assays are described as follows:

25

Example 1*CDK1 Screening Assay*

A kinase reaction mixture was prepared containing 50 mM Tris-HCl pH = 8, 10 mM MgCl₂, 0.1 mM Na₃PO₄, 1 mM DTT, 10 µM ATP, 0.025 µM biotinylated histone-H1 peptide substrate and 0.2 µCuries per well ³³P-γ-ATP (2000-3000 Ci/mmol). 70 µL of the kinase reaction mixture was dispensed into the well of a streptavidin coated FlashPlate™ (Cat. # SMP103, NEN, Boston, MA). Then 1 µL of test compound stock in 100% DMSO was added to the wells resulting in a final concentration of 1% DMSO in the reaction with a 100 µL final reaction volume.

10 The CDK1:Cyclin-B protein was then diluted in 50 mM Tris-HCl pH = 8.0, 0.1% BSA at a concentration of 1 ng per µL and 30 µL (30 ng enzyme per test well) was added to each well to initiate the reaction. The reaction was incubated for one hour at 30 °C. At the end of the 1h incubation, the reaction was terminated by aspirating the mixture from the plate and washing the wells twice with PBS containing 100 mM EDTA. The histone-H1 biotinylated peptide substrate became immobilized on the Flashplate™ and the incorporation of ³³P-γ-ATP was measured by reading the plate on a scintillation counter. Inhibition of the enzymatic activity of CDK1 was measured by observing a reduced amount of ³³P-γ-ATP incorporated into the immobilized peptide.

15 The CDK1 used was isolated from insect cells expressing both the human CDK1 catalytic subunit and its positive regulatory subunit cyclin B (New England Biolabs, Beverly, MA, Cat. # 6020).

Example 2*VEGF-R2 Screening Assay*

The VEGF-R kinase assay was carried out using the CDK kinase assay procedure except that the enzyme was replaced with the VEGF-R2 fusion protein containing a polyhistidine tag at the N-terminus followed by amino acids 786-1343 of the rat VEGF-R2 kinase domain (GenBank Accession #U93306).

Example 3*Aurora-A Screening Assay*

30 The Aurora-A kinase assay was carried out using the CDK kinase assay procedure except that the enzyme was replaced with the full length protein encoding the

murine Aurora-A (Accession# GB BC014711) expressed and purified from sf9 insect cells.

Example 4

HER2 kinase Screening Assay

5 The HER2 kinase assay was carried out using the CDK kinase assay procedure except that the enzyme was replaced with a HER2 construct containing a polyhistidine tag at the N-terminus followed by 24 additional amino acids and the HER2 cytoplasmic domain beginning at amino acid 676 (Accession #M11730) to the end.

Example 5

10 *RET kinase Screening Assay*

The RET kinase assay was carried out using the CDK kinase assay procedure except that the enzyme was replaced with a construct encoding the RET cytoplasmic domain consisting of the last 492 amino acids of the intracellular domain of the RET tyrosine kinase (accession #X12949) containing an N-terminal histidine tag was expressed and purified from Hi5 insect cells.

Results of assays performed on compounds described above are provided below in Table 1. An IC₅₀ listed as >0.1, >1, or >10 means no observed 50% inhibition at the highest test concentration. An IC₅₀ listed as ~1 or ~10 means approximately 50% inhibition was observed at the highest test concentration. ND means the compound was not tested in the assay specified.

Assay to Measure Inhibition of Cell Proliferation

The ability of a test compound to inhibit the proliferation of cell growth was determined by measuring incorporation of ¹⁴C-labelled thymidine into newly synthesized DNA within the cells. This method was used on cell lines derived from carcinomas originating from several tissues such as **HeLa** cervical adenocarcinoma (American Type Culture Collection (ATCC), Virginia, Cat. #CCL-2), **A375** malignant melanoma (ATCC CRL-1619), **HCT-116** colon carcinoma (CCL-247). In this way the effect of a compound on cell growth of cells with many different phenotypes can be determined. Cells were trypsinized and counted and 3000-8000 cells were added to each well of a 96-well CytoStar tissue culture treated scintillating microplate (Amersham #RPNQ0160) in complete medium in a volume of 100 μL. Cells were incubated for 24 hours in complete medium at 37 °C in an atmosphere containing 5% CO₂.

Next, 1 μL of test compound in 100% DMSO was added to the wells of the plate. DMSO only was added to control wells. Cells were incubated for 24 more hours in complete medium at 37 °C in an atmosphere containing 5% CO₂. Methyl ¹⁴C-thymidine 56 mCi/mmol (NEN #NEC568 or Amersham #CFA532) was diluted in complete medium and 0.2 uCi/well was added to each well of the CytoStar plate in a volume of 20 ul. The plate was incubated for 24 hours at 37 °C plus 5% CO₂ in drug plus ¹⁴C-thymidine. The contents of the plate were discarded into a ¹⁴C radioactive waste container by inverting the plate and the plate was washed twice with 200 μL PBS. 200 μL of PBS is added to each well. The top of the plate was sealed with a transparent plate sealer and a white plate backing sealer (Packard #6005199) was applied to the

bottom of the plate. The degree of methyl ^{14}C -thymidine incorporation was quantified on a Packard Top Count.

Antiproliferative effects of the compounds described above are provided below in Table 2.

In Vivo Models – Inhibition of Tumor Growth

The *in vivo* effect of a compound on the growth of human tumor cells can be evaluated by implanting human tumor cells into the hindflank of athymic mice and administering test compound to the mice. Human tumor cells originating from a variety of different tumor types, such as A375 human melanoma cells, are implanted subcutaneously into the hindflank of male athymic mice (Charles River) and allowed to establish a sizeable tumor for 6-10 days as determined by caliper measurements. Test compound is then administered by injecting the compound formulated in an appropriate vehicle intraperitoneally into the mice once a day for 30 days. The test compound can also be administered by other routes such as orally, sub cutaneously or by intravenous infusion. The size of the tumor in this study is measured every four days and the degree of inhibition is determined by comparing drug-treated animals to animals that are injected with vehicle only.

The synergistic action or enhancement of conventional chemotherapeutic agent by a test compound can also be determined with this model by comparing animals treated with the standard therapy alone to animals treated with test compound plus the same standard therapy. An additive effect on the delay of tumor growth will be observed if synergistic action due to test compound is occurring.
